C4.5 (avec le gain d'information, cette implementation est juste pour montrer que l'utilisation du gain d'information a donné des resulats plus efficace que l'utilisation du rapport de gain) - Ce model implementé a l'aide des notions de la programmation orientée objet, puisque je vois que c'est plus facile de comprendre le code et de le modifier (la programation fonctionnelle pour implementer ce type de model rend les choses plus compliquées)

Import des bibliothèques

```
import numpy as np
import seaborn
from sklearn.model_selection import train_test_split
from sklearn.metrics import accuracy_score
```

Données

```
col_names = ['sepal length', 'sepal width', 'petal length', 'petal
width', 'type']
data = seaborn.load_dataset("iris", skiprows=1, header=None,
names=col_names)
```

Class noeud

```
class Node():
    def __init__(self, feature_index=None, threshold=None, left=None,
right=None, info_gain=None, value=None):
        # constructeur

        # pour les noeuds de décision
        self.feature_index = feature_index
        self.threshold = threshold
```

```
        self.left = left
        self.right = right
        self.info_gain = info_gain

        # pour les noeuds feuilles
        self.value = value
```

Class Arbre de decision

```
class DecisionTreeClassifier():
    def __init__(self, min_samples_split=2, max_depth=2):
